# Introduction

It is well-established that repetition of heat stress exposure has been shown to facilitate adaptations to the heat but these protocols have tended to be of a fixed work intensity, continuous exercise, long-term in duration (>7 days) and use hydration. Secondly, there is limited information on the potential use of heat acclimation as a training method for human performance in thermoneutral conditions [1]. Therefore, the aims of this study were to investigate the effectiveness of short-term heat acclimation (STHA) for 5 days, using the controlled-hyperthermia technique with dehydration, on intermittent exercise in thermoneutral and hot environments.

### Methods

Ten, healthy, active, moderately-trained males (Mean (SD); Age 25.6 (8.9) yrs; Height 180.7 (5.6) cm; Body Mass 83.2 (10.8) kg;  $\dot{V}O_{2\,max}$  45.3 (6.5) mL.kg<sup>-1</sup>.min<sup>-1</sup> and resting cardiac output 6.3 (1.8) L.min<sup>-1</sup>), participated in a STHA programme. This consisted of 90 minutes dehydration heat acclimation (no fluid intake) for 5 consecutive days (39.5 °C; 60% rh), using the controlled-hyperthermia technique (~rectal temperature [T<sub>re</sub>] 38.5 °C) [2]. The pre and post testing Exercise Stress Test (EST) consisted of 45 minutes of intermittent exercise (nine phases of 5 minutes). Including resting, walking, moderate and high intensity running) on a motorised, h/p Cosmos treadmill; and nine 6 second (s) maximal sprints on a Watt Bike, as a repeated, maximal sprint performance test. The EST was followed by a running, incremental test to exhaustion. This EST intermittent protocol was adapted from exercise intensities of professional football players [3]. The EST was repeated in controlled conditions (C; 11  $^{\circ}$ C 45% rh); pre and post STHA in thermoneutral (TN; 11  $^{\circ}$ C 45% rh) and hot environments (H; 35  $^{\circ}$ C 45% rh). Data analysis was by paired t-test and reported as the mean differences with 95% confidence intervals (95%CI).

#### Results

Post STHA, in the H trial at 45-min there was a decrease in  $T_{\rm re}$  by -0.2 °C (95%CI: -0.40 to 0.00 °C; p=0.03), cardiac frequency (-3: -5 to -1 b.min<sup>-1</sup>; p=0.01) and RPE (-2: -3 to -1 units; p=0.01). Mean average power (MavP) increased in sprints 7 (111: 25 to 197 W; p=0.01) and 9 (240: 9 and 489 W; p=0.04). The increase in Sprint 8 (87: -8 to 182 W; p=0.06) and time to exhaustion (208: -24 to 439 s; p=0.06) were close to significance. In the TN trial, increased MavP for sprint 9 (67: 2 to 131 W; p=0.04) and time to exhaustion (43: 1 to 85 s; p=0.04) were reported. There was limited change in the C conditions across all nine sprints (p>0.05) and for time to exhaustion (-31: -72 to 11 s; p=0.12).

# **Discussion**

Short-term heat acclimation (5 days) with dehydration, using the controlled-hyperthermia technique, is effective for physiological adaptations during intermittent exercise in a hot environment. Furthermore, it has resulted in an increase in intermittent and endurance exercise performance in hot and thermoneutral conditions.

## Conclusion

Short-term heat acclimation is effective for intermittent exercise in the heat. It may be a useful training method for human performance in thermoneutral conditions.
